1. Outline

1.1 Introduction

AT3051 series smart pressure transmitter is a smart multi-functional digital inst rument researched & developed by AUTO. It's uniquely designed from advanced single-chip technology and smart digital sensor technology on the basis of mature and reliable sensor technology.

Its core component is 16 bit single-chip, of whose strong function and high-speed calculation will guarantee transmitter's quality. The whole design focus on reliability, stability, high-precision and intelligence. It also meets field industrial application requirements. Software adopts digital signal processing technology, enhancing transmitter good anti-interference ability, zero point stability, Zero Sensitive Capability (ZSC) and Temperature Sensitive Capability (TSC).

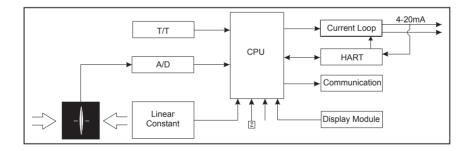

1.2 Characteristics

AT3051 not only has excellent anti-in terference ability, zero point stability, Zero Sensitive Capability (ZSC) and Temperature Sensitive Capability (TSC), but also HART communication capability from optional HART modules.

2. Principle and Wiring Diagram

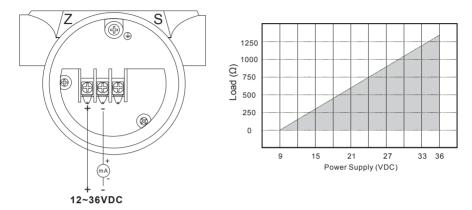

2.1 Principle

When pressure or differential pressure is externally input, sensor's resistance will change and be converted into frequency signals by digital signal, and then sent to microprocessor. The microprocessor will output a current control signal to current output control circuit after its calculation, turning into 4-20mA analog current output and displays finally.

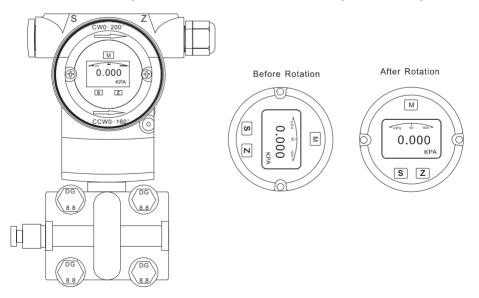

2.2 Wiring Diagram

AT3051 output is 2-wire 4-20mA output.

3. Transmitter Rotation

Available clockwise rotation angle: $0-200^{\circ}$; available counterclockwise rotation angle: $0-160^{\circ}$. See figure below:

4. Interface Display

4.1 Normal Display

This transmitter can be rotated clockwise/counterclockwise 180° for your convenience to check display.

Code	Code Function
PV	Normal Display (Mesuring Status)
%	Percentage
InH2O, InHg, FtH2O, mmH2O, mmHg, PSI, Bar, mBar, g/cm2, Kg/cm2, Pa, Kpa, Torr, ATM, Mpa, InH20@4°C, MH20@4°C, MH2O, mHg, M, Cm, mm, Special.	Display measuring unit. "Special" means customer's unit can be written by HART.

4.2 Setting Status

PA /	Code	Code Function
	2	Window code ("2": unit selection window)
' /	KPA	Measuring unit

4.3 Keypad

Key Name	Button Sign	Setting Function	
SET	Μ	Enter Parameter setting; save configuration; shift to next page	
MOVE	Ζ	Move the cursor to the right	
UP	S	Increase the values and decimal point position	

1. Hold Z button for 2 seconds then release to enter main menu settings.

If there is no response for 10 seconds in the window 0, it will return to the normal display automatically. If there is no response for 2 minutes in the non-window 0, it will return to the normal display automatically.

- 2. Hold [M + Z] button for 5 seconds then release to enter menu setting window 6 for zero clearance. Press S botton and choose "YES" to clear zero.
- 3. Hold S+Z button for 5 seconds then release and enter the menu setting window 7 for zero shift and full span shift.

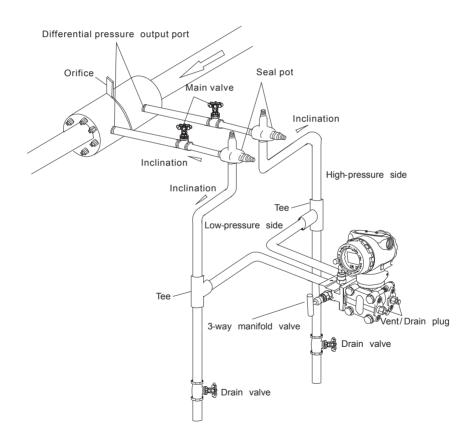

Hold Z button for 5 seconds then release to finish Zero Shift; hold S button for 5 seconds then release to finish full span shift.

5. Specific Application and Typical Installation

5.1 Typical Installation for Flow Measurement

This illustration shows a typical example for steam flow rate measurement. Differential pressure transmitter is located below the differential pressure out put port of the process pipe.

After piping work, make sure that the connecting pipe, 3-way manifold valve and transmitter have no pressure leaks.Pipe installation for steam flow rate measurement is as follow:

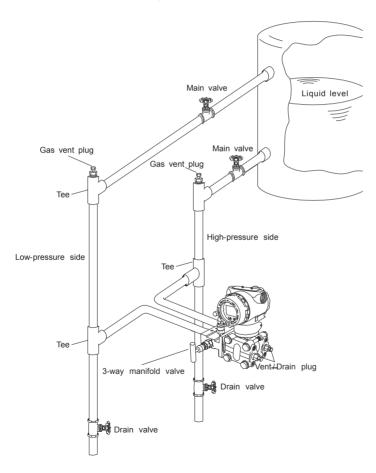

5.2 Typical Installation for Liquid Level Measurement

When using dry-leg method, connect the high-pressure side of the transmitter to the lower part of the tank. Connect the low-pressure side to the gas-sealing pipe of the tank.

After completing piping work, check for pressure leaks around the connecting pipe, the transmitter and 3-way manifold valve. The following shows a typical installation.

Always connect the high-pressure side of this transmitter to the lower part of the tank.

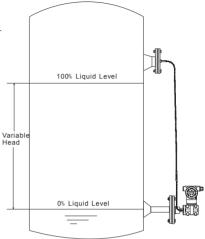

Install this transmitter below the lowest liquid level to be measured.

6. AT3051 Applications

6.1 Closed Tank

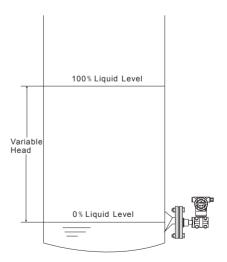

When it is closed tank, there will be pressure given inside tank. It's supposed to choose either AT3051LT or AT3051RD. When setting the zero point, make sure the diaphragm area of high-pressure side to be fully wet with measured liquid for higher accuracy.The center diaphragm of high-pressure side is the right zero point. See figure as below:

6.2 Open Tank

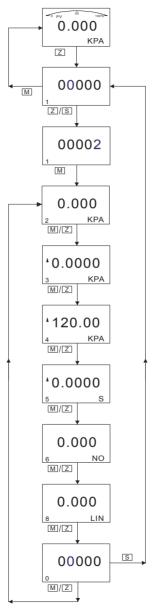

When it is open tank, liquid above will be directly contacted with atmosphere. It's supposed to choose directly-connected AT3051.

When setting the zero point, make sure the diaphragm area of high-pressure side to be fully wet with measured liquid for higher accuracy. The center diaphragm of high-pressure side is the right zero point. See figure as below:

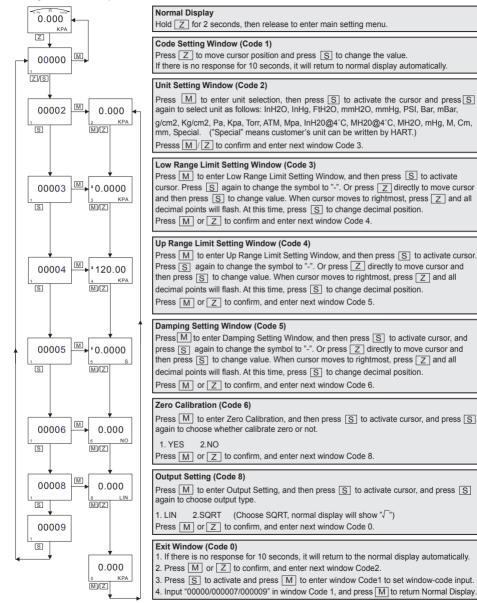

7. Operation Instructions

7.1 Operation Flow Chart

7.2 System Menu Operation

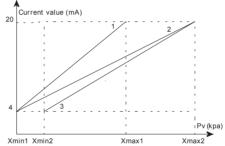

(1) Up/Low Range Limit Correspondence to 4-20mA

In settings, if necessary, low/up range Limit will be given standard current value (4mA/20mA) respectively. Preconditions: Two reference voltages should be supplied by processing or pressure transmitter. After setting pressure transmitter, actual setting range might be different from the range marked in measuring plate. For different serial number and measuring range, turndown ratio can be up to 1:100.

Measuring pressure is linearly related to output current. Current value can be calculated from given formula below. I means output current, P measured pressure, ME up limit value and MA low limit value.

$$I = \frac{P - MA}{ME - MA} \times 16mA + 4mA$$

Actually because of change of measur ing demands or conditions, transmitter's range needs to be changed too. However, changing range means changing slope of transmitter's input/output, like from curve 1 to curve 2, it means up range limit increasing adjustment; from curve 2 to curve 3, it means low range limit increasing adjustment. See figure below:

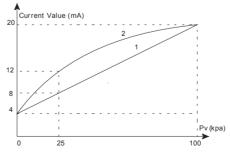

(2) Damping Settings

Available setting time is 0-32s. The bigger this value is, the more stable measuring value will be (Flunctuation will be more moderate). Increasing damping time will lead to signal delay.

(3) Zero Calibration

Because of zero drift, the measured zero point will not be 0. Zero calibration enhances better measuring accuracy. (4) Output Settings

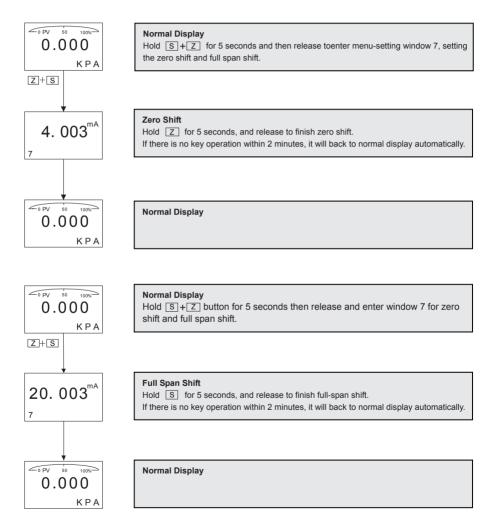

e.g. Transmitter's pressure range "0-100kpa", if output setting as "lin", current output will be curve 1. If set "sqrt", current output will be curve 2. For example, if pipe pressure as 25kpa, under "sqrt" condition current output will be 12mA.

7.3 How to Set Positive Shift and Negative Shift

7.3.1 Zero Shift and Full Span Shift Operation

This is hidden window, so it can not display if you directly input code 7 in the code window. You have to hold $\boxed{S} + \boxed{Z}$ for 5 seconds until it displays.

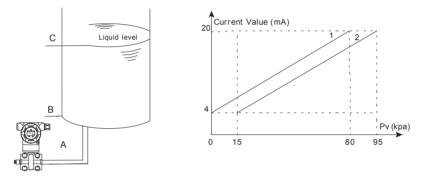

When it comes to actual measurement, as request from customer, the initial measuring point needs to be shifted to a certain value (positive or negative). This is so called zero shift and full span shift.

(1) Zero Shift (Elevated Span / Suppressed Span)

After zero shift, measuring range will change toward positive (increase) direction, namely positive shift. For example, pressure transmitter is installed at point A, the liquid head AB that is formed by medium that comes into pressure-guiding pipe will send a pressure to transmitter, turning the measuring result into AC's pressure (measured pressure BC plus liquid head's pressure). At this time, when liquid level is at point B, give positive zero shift to transmitter, the initial value of corres ponding 4-20mA will move from point A to point B, making it convenient for customer to control application.

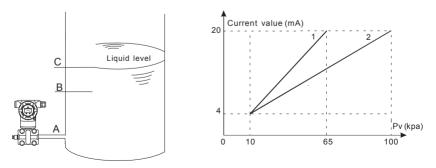

If trasmitter's range is 0~80kpa and AB pressure of pressure guiding pipe is 15kpa, after zero shift, change will be like figure below: curve 1 to curve 2.

(2) Full Span Shift

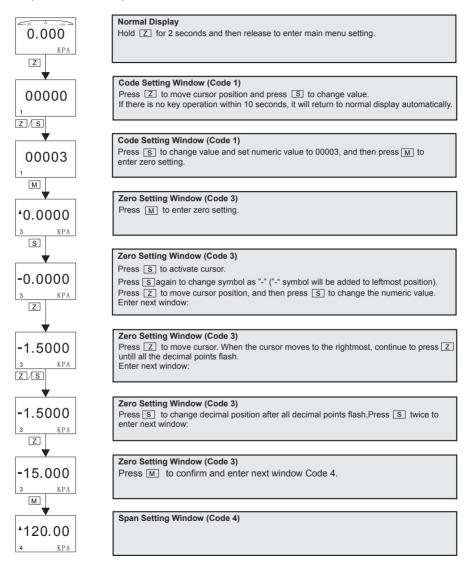

After full span shift, measuring range will change toward negative (decrease) direction, namely negative shift. For example, when pressure transmitter measures liquid level's pressure and operator just needs the pressure of level AB (lower than AC pressure), full span shift can be start.

If trasmitter's range is 10~100kpa and AB pressure of liquid level is 65kpa, after full span shift, change will be like figure below: curve 2 to curve 1.

7.4 How to set Decimal Point and Minus Value

Example: Set zero as "-15Kpa".

7.5 Displayed Variables Settings

LCD can be set to display "Process Variable", "mA value", "%". These 3 displaying contents can be displayed either constantly one of them or alternatively 2 of them.

If first displayed variable and second displayed variable are the same, this will be constant display.

If first displayed variable and second displayed variable are different, this will be alternative display (interval is 4 secs).

In normal display interface, hold S button to change displayed variable (In bottom left corner, function code is 30.).

Different variables in normal interface means alternative display, for example, "process variable" and "mA value" display alternatively (first variable: "process variable"; second variable: "mA value").

Same variables in normal interface means constant display, for example, "process variable" displays constantly (first variable and second variable are both the same: "process variable").

e.g. 1 When displayed contents are "process variable" and "mA value", which means alternative display, to change to constant display and make displayed content as "process variable", you need to change "mA value" to "process variable", namely, making the first variable same as the second.

Procedures: When screen displays "mA value", hold S and do not release until screen shows "process variable". Namely changing "mA value" to "process variable". At this time, screen will constantly display "process variable".

e.g 2 When displayed contents are "process variable", which means constant display, to change to alternative display and make displayed content as "process variable" and "mA value", you need to change "process variable" to "mA value", namely, making the first variable different from the second.

Procedures: When screen displays "process variable", hold S and do not release until screen shows "mA value". Namely changing "process variable" to "mA value". At this time, screen will alternatively display "process variable" and "mA value".

8. Flow Measurement Settings

Differential pressure transmitter measures flow and displays flow rate. As long as flow range and differential pressure's range is certain, flow can be measured and flow rate can be displayed.

If your purchased product has HART communication function, you can set parameters by yourself. As a result, to measure flow, it's recommended to order this product that has HART communication function.

Let's take an example of HART function settings

EX.1: Differential pressure's range is 0~500mbar and corresponding flow range is 0~200M3/H.

Steps: 1. Build Hart communication, Run software.

- 2. In Configuration column, single click Range Range values PV Unit Special.
- 3. Input up range value and low range value, namely "PV URV"=200.000 and "PV LRV"=0.000.
- 4. Click "write" to save settings.

Shown as below:

Informations	
Configuration	
ORange	Sensor Information: PV Snsr s/n: 16777215

6. In "User Unit", set it as "M3/H".

7. Input "Coefficient" value.

The calculation formula of Coefficient value = $\triangle P(Kpa)/Max$ Flowrate.

500mbar=50Kpa

Now coefficient value is =50/200=0.25 and you should input 0.25 in Coefficient.

8. Click write to save settings.

Shown as below:

informations Configuration		
lonitor	Small signal cut:	Temp value cali.:
ransmitter Cali.	the value range is $0 \sim 3$	This function is used to adjust the
laintenance	Select: OFF	temp value of sensor, so that it is the same to the actual temp.

	Coefficient: 0.25000000 * kPa	

Note: If actual value and displayed value are different, please trim coefficient value.

EX.2: Differential pressure's range is 0~6000mmH2O and corresponding flow range is 0~300NM3/H.

Steps: 1. Build Hart communication . Run software.

- 2. In Configuration column, click Range Range values PV Unit Special
- 3. Input up range value and low range value, namely "PV URV"=300.000, "PV LRV"=0.000.
- 4. Click "write" to save settings.
- 5. In Configuration column, click "Output func" Output PV Related Var.of Xfer fnctn ----> Related Var.of Xfer fnctn ----> choose "Square Root".
- 6. In "User Unit", set it as "NM3/H".
- 7. Input Coefficient value.

The calculation formula of Coefficient value $= \triangle P(Kpa) / Max$ Flowrate.

6000mmH2O=58.84Kpa

Now coefficient value is =58.84/300=0.196 and you should input 0.196 in Coefficient.

8. Click write to save settings.
